5 CROSS REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of U.S. Provisional Application No. 60/225,600, filed August 15, 2000, which is incorporated herein by reference in its entirety.

BACKGROUND OF THE INVENTION

10 Field of the Invention

This invention relates to packetized telecommunication networks and more particularly to use of a centralized feature platform.

Description of the Related Art

When a telecommunication system receives a call, the system often needs to
15 authenticate the call in some manner, to ensure, e.g., the validity of a calling card
number, a personal identification number or some other credential associated with the
call. Traditionally, in circuit switched telephone networks the standard call flow for
an authentication service for a calling card is as follows. Assume a calling card call is
received in a telephone network. The call is connected, to a facility having
20 authentication capability, e.g., an Interactive Voice Response (IVR) function that
prompts the caller for pertinent information, such as the calling card number and the
number the caller is trying to reach. The IVR function either validates the call or
drops the call. If the call is validated by the authentication facility, then the call is
connected to its calling destination through the authentication function. Thus, as
25 shown in Fig. 1, the facility 101 that validated the call functions as an in-line relay
between the call origin 103 and the call destination 105 since the call is still connected
through the authentication facility.

While that solution may be acceptable for switched circuit networks (e.g., for telephone systems with class 4 and above circuit switches) which tend to have a lot of "edge centralization" on the network, for emerging packet switched based telephone networks, placing complex functionality in multiple places on the edge of a network can be expensive and therefore undesirable.

Accordingly, it would be desirable to provide the functionality of feature services such as authentication without the cost and complexity of duplicating resources in multiple places in a packet-based telecommunications network.

SUMMARY OF THE INVENTION

Accordingly, in one embodiment, the invention provides a method that includes receiving a call at a gateway of a packetized telecommunication network, directing the call to connect to a feature platform via the network and performing a service related to the call in the feature platform. After the service is performed, the call is transferred to another location in the network to provide a connection between the gateway and the other location, which connection is independent of the feature platform. The service may be an authentication service.

In another embodiment the invention provides a method of authenticating a call received at a packetized voice network comprising receiving the call requiring authentication at any one of a plurality of ingress points for the network, routing the call from the one ingress point to an authentication server, authenticating the call in the authentication server and routing the call to an egress point on the network, instead of the authentication server, after authenticating the call.

In another embodiment, the invention provides a communication network comprising a packet switched network including one or more gateways coupled to receive calls for the network requiring a feature service. The communication network includes a feature platform that is coupled to connect to the calls requiring the feature service received at the one or more gateways, provide the feature service and cause the calls to be redirected to another point on the network after the feature service is provided.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention may be better understood, and its numerous objects, features, and advantages made apparent to those skilled in the art by referencing the accompanying drawings, in which the use of the same reference symbols in different
 5 drawings indicates similar or identical items.

Fig. 1 illustrates the in-line relay connection of a prior art authentication service.

Fig. 2 illustrates a communication network configured with a centralized feature platform for authentication and/or other services.

10 Fig. 3 illustrates a call flow in the system of Fig. 2 according to one embodiment of the invention.

DESCRIPTION OF THE PREFERRED EMBODIMENT(S)

Referring to Fig. 2, in one embodiment of the invention, a packet-based communication network 201 provides telecommunication services operating in
 15 accordance with a communication standard such as the International Telecommunications Union (ITU) H.323 standard, which provides for packet-based multi-media communication including transmission of real-time audio, video, and data communications. The H.323 standard specifies the components, protocols, and procedures providing multi-media communication over a variety of packet-based
 20 networks including Internet Protocol (IP)-based networks. The H.323 standard can be used for transmission of various combinations of audio, video and data, including audio only (for IP telephony applications); audio and video; audio and data; or audio, video and data. Note that the use of the H.323 standard in the described embodiments is exemplary only. Other emerging or existing standards for packet-based voice,
 25 video or data communication, may also be used to implement the teachings described herein.

Referring still Fig. 2, packet-based network 201 includes a plurality of ingress and egress points identifies as gateway 0 (GW0) 203, gateway 1 (GW1) 205 and gateway 2 (GW2) 207. One or more of the gateways, e.g., gateway 203, may be

connected via trunk line 209 to a central office 211 of a public switched telephone network (PSTN). Each gateway provides a connection between two different kinds of networks. For instance, gateway 203 provides a connection between the PSTN and packet based network 201. In order to connect the different networks, the gateway

5 has to translate protocols appropriately for call setup and release, and e.g., convert data to and from the various encoding and compression techniques utilized on the different networks. Such gateways are known in the art and utilized for example, in H.323 based networks interfacing to a PSTN. The gateways may also connect one packet-based network to another packet-based network.

10 In addition to the gateways, exemplary packet based network 201 includes gatekeeper 213. Gatekeeper 213 provides a control function within network 201. For example, gatekeeper 213 may provide such network management services as call routing, addressing, bandwidth management, accounting and billing. Network 201 also includes feature platform 215 which provides a centralized location for feature

15 services. For example, feature platform 215, in one embodiment, provides an authentication service for calls coming into the gateways. Rather than have each gateway have the necessary support to provide various feature services, the present invention provides a centralized location to provide such services. That allows each of the gateways to be less complex and easier to maintain. It is easier to change one

20 or more centralized locations rather than each of the gateways in the system for modifications, upgrades, maintenance and expansion.

The call flow of an exemplary authentication service will now be described for the network illustrated in Fig. 2. Referring to Fig. 3, assume a calling card call 301 is received at gateway 203 through central office 211. Gateway 203 requests from

25 gatekeeper 213 via query 303 an IP address that corresponds to the 800 number dialed by call 301. Assume in the example that the 800 number is utilized by calling cards. Based on that number, gatekeeper 213, utilizing a routing table 214, informs gateway 203 via packet(s) 305 that the call should be connected to feature platform 215 for authentication. Call 301 is then connected to feature platform 215 via the packet

30 switching network as shown at 307.

Feature server 215 may include such capability as voice prompting that prompts the user to enter needed additional information to complete the authentication

process, such as a calling card number. The caller may also be prompted for the destination number if that has not already been entered, as shown at 309. That prompt is routed through the packet-based network to gateway 203, which converts the prompt to an appropriate protocol for the PSTN network. There may be multiple prompts and responses depending on the exact nature of the service provided. For example, the caller may be prompted for a calling card number, a destination number, a credit card, a personal identification number or some other credential required to complete the call. The PSTN provides the responses as DTMF (Dual Tones Multi-Frequency) tones used by touch-tone telephones which are captured by the gateway. The captured DTMF tones are used to validate or reject the call. If validated, DTMF capture is used for the destination number or other information provided by the caller.

Once feature platform 215 has authenticated the call, i.e., determined that the calling card number is legitimate and obtained the destination number, it can disassociate itself from the call. That is, feature platform 215, based on the destination number provided by the calling party, requests appropriate routing information from gatekeeper 213 via packet(s) 311. Gatekeeper 213 responds with packets 313, which include the IP address for the destination number. Assume the destination for the call is a telecommunications network coupled to gateway 205. The call transfer information is provided by feature platform 215 (or by gatekeeper 214) to gateway 203 so the call can be routed to connect gateway 203 to gateway 205 via packet(s) 317. Thus, call 301 is now connected through packet based network 201 to gateway 205 without any need for further participation of feature platform 215 in the link between gateway 203 and gateway 205. Note that the destination for the call could also be internal to network 201 rather than external through gateway 205.

The transfer facility to redirect the call to the other egress point (e.g., gateway 205) from feature platform 215 may utilize a transfer mechanism provided by a number of different underlying protocols. In one environment, the transfer facility provided under H.450.2 may be utilized, which is a supplemental standard for H.323. In a load sharing environment, the transfer facility provided in H.450.3 may be utilized. Transfer capabilities provided by various emerging protocols, such as Simple Gateway Control Protocol (SGCP), Media Gateway Control Protocol (MGCP), Megaco, Session Initiation Protocol (SIP), which is a signaling protocol for

Internet conferencing and telephony, or Internet Protocol Device Control (IPDC) protocol, may be used to redirect the call. The particular transfer facility used is not important as long as the functionality of redirecting the call according to the teachings herein is accomplished.

5 Feature server 215 is no longer needed for the call and thus packets for the remainder of the call are not routed to or through feature server 215. Thus, feature server 215 is available again to provide services requested by any gateway (or any other node on the network) that requires the services provided without having to serve as a relay for the remainder of the authenticated call. While the authentication service
10 may validate the call, which results in redirecting the call to an egress point or other point on the network, it is also possible that the authentication service determines that the call should be dropped. In that case, the feature server informs both the gateway and the gatekeeper.

The authentication service is not limited to calling cards, PIN numbers or
15 other user entered data. In fact, the authentication service may validate that the caller is authorized to access network based on Automatic Number Identification (ANI) information (i.e., the calling number) to verify that the number is authorized for a particular type of service. ANI information is used in conventional telephone networks to provide such services as caller ID. For example, a subscriber may
20 subscribe to a long distance service carried over packet-based network 201, the ANI being used to authenticate that the call is from a subscriber.

Other types of services can also benefit from the ability to provide a central intelligent function which can then disassociate itself from the subsequently connected call. Another example of such a service is a follow-me service in which a
25 subscriber is reached at one number regardless of the actual location of the subscriber. Thus, a received call can be routed to a wireline, a cellular number, voice mail, email, pager or other number associated with the called number. The service may implement a time manager for routing. If the feature platform determines that the call should be routed to another location, the call is redirected to that location and feature platform
30 215 can be disassociated from the call. That is, it does not function as an in-line relay for the call. Additionally, the feature server could be used for a best effort follow-me service, in which the system has a list of possible locations and methodically tries

numbers until the subscriber is reached. Also, the feature server can provide a management function capable of being called into and provided a current location for the subscriber.

Other features may be supported by feature platform 215. For example, calls
 5 may be routed to different numbers based on time of day, vacation plans or any other of a variety of conditions that can be specified for call routing. Any number that is received that requires special service features can be routed to a centralized feature platform that can provide the services requested. For example, assume a call is received into a gateway over trunk 209. When that call is received, the gateway
 10 requests a look-up in the routing table and the call is routed to feature server 215, if the called number is a number associated with a follow-me or other feature service.

In another application, the centralized feature service platform system can also be used for pay-per-stream distribution of media. In such an application, the centralized feature service platform authenticates an endpoint such as a set-top box
 15 ordering the particular media such as a movie. Once the endpoint is authenticated, the feature service platform can redirect the connection so a feature server actually providing the streaming media is coupled to the endpoint. Note that the ordering device does not necessarily have to be the endpoint to which the streaming media is directed. In addition, the endpoint may be inside or outside of the network.

A variety of other applications can be supported by a centralized feature
 20 server. For example, the centralized feature service platform can provide backend clustering capabilities on messaging services, allowing providers a way of redirecting voice mail/messages to an alias associated with site. It can also setup conferences without centralization when the protocol used supports multiple streams. The feature
 25 platform can also be coupled with powerful databases capable of announcing current ratings or prices.

Thus, such feature services as debit/calling card, one number/follow-me, call back service, call screening, student phone home, as well as other similar services commonly offered in the circuit-switched world can advantageously use the
 30 centralized feature platform described herein. The centralized feature platform is also

useful for call centers since frequently call center agents are not centralized and companies use large PBXs to connect callers and agents.

In one application in which calls originate in the network and are directed to outside the network, for example in a tele-marketing environment, the centralized feature platform can be used to control calling to numbers external to the network. Thus, instead of providing an authentication service for an incoming call into the network, the feature platform provides call control for outgoing calls from the network. The call control include determining what numbers are called. As in previous embodiments, once the calls are connected, the established calls are not routed through the feature platform but redirected for connection independent of the feature platform to an appropriate call agent.

The description of the invention set forth herein is illustrative, and is not intended to limit the scope of the invention as set forth in the following claims. Other variations and modifications of the embodiments disclosed herein, may be made based on the description set forth herein, without departing from the scope and spirit of the invention as set forth in the following claims.

WHAT IS CLAIMED IS:

- 1 1. A method comprising:
2 receiving a call at a gateway of a packetized network;
3 directing the call for connection to a feature platform via the network;
4 performing a service related to the call in the feature platform; and
5 after performing the service, transferring the call to another location in the
6 network to provide a connection between the gateway and the other
7 location, the connection being independent of the feature platform.

- 1 2. The method as recited in claim 1 wherein the packetized network is a
2 voice network.

- 1 3. The method as recited in claim 1 further comprising providing an
2 authentication service as the service in the feature platform.

- 1 4. The method as recited in claim 3 wherein the authentication service
2 validates a calling card number.

- 1 5. The method as recited in claim 3 wherein the authentication service
2 validates a personal identification number.

- 1 6. The method as recited in claim 3 wherein the authentication service
2 includes voice prompts.

- 1 7. The method as recited in claim 3 wherein the authentication service
2 utilizes Automatic Number Identification (ANI) information as a basis for
3 authentication.

- 1 8. The method as recited in claim 1 further comprising providing a
2 follow-me service as the service.

- 1 9. The method as recited in claim 1 wherein the other location is an
2 egress gateway.

1 10. A communication network comprising:
2 a packet switched network including one or more gateways coupled to receive
3 calls for the network requiring a feature service; and
4 a feature platform coupled to connect to the calls received at the one or more
5 gateways, provide the feature service and cause the calls to be
6 redirected to another point on the network after the feature service is
7 provided.

1 11. The communication network of claim 10 wherein the feature service is
2 an authentication service.

1 12. The communication network as recited in claim 11 wherein the
2 authentication service includes voice prompting.

1 13. The communication network as recited in claim 11 wherein the
2 authentication service utilizes Automatic Number Identification (ANI) information for
3 authentication purposes.

1 14. The communication network of claim 10 wherein the feature service is
2 a follow-me service.

1 15. The communication network as recited in claim 10 wherein the call is
2 redirected from the feature platform to the other location on the network using a
3 media gateway control protocol.

1 16. The communication network as recited in claim 10 wherein the call is
2 routed to the feature platform according to a destination number identification service
3 (DNIS).

1 17. The communication network as recited in claim 10 wherein the call is
2 received from a publicly switched telephone network (PSTN).

1 18. A method of authenticating a call received at a packetized voice
2 network comprising:

receiving the call requiring authentication at any one of a plurality of ingress points for the network;
 routing the call from the ingress point to an authentication server;
 authenticating the call in the authentication server; and
 routing the call to an egress point on the network instead of the authentication server after authenticating the call.

19. A method of operating voice traffic bearing packet switched network, the method comprising:
 receiving at a gateway to a packet-switched network, an information stream including encoded voice-band traffic originating from a voice terminal outside the packet-switched network;
 directing the information stream over the packet-switched network to an authentication service and thereby establishing a connection between the voice terminal and the authentication service; and
 upon authentication by the authentication service, dissociating the information stream from the authentication service, re-directing the information stream via the packet-switched network to establish a connection with a target device.

20. The method as recited in claim 19, further comprising:
 authenticating a credential associated with the information stream using the authentication service.

21. The method as recited in claim 20,
 wherein the authenticating includes bi-directional communication of encoded voice-band traffic between the voice terminal and the authentication service via the gateway.

22. The method as recited in claim 19,
 wherein the directing is based, at least in part, on first destination identifier supplied with the encoded voice-band traffic originating from the voice terminal.

1 23. The method as recited in claim 22,
2 wherein a second destination identifier is supplied from the voice terminal
3 coincident with the authenticating; and
4 wherein the second destination identifier is selective for the target device.

1 24. The method as recited in claim 22,
2 wherein the first destination identifier includes a phone number corresponding
3 to the authentication service; and
4 wherein a second destination identifier selective for the target device is
5 supplied from the voice terminal coincident with the authenticating.

1 25. A method of operating a packet switched network comprising:
2 receiving at an authentication service in the network a request to authenticate
3 an endpoint for a pay-per-stream distribution of media;
4 upon authentication by the authentication service, directing the pay-per-
5 stream distribution of media from a feature server in the network
6 providing the pay-per-stream distribution of media as an information
7 stream; and
8 providing via the packet-switched network a connection between the feature
9 server providing the information stream and the endpoint.

1 26. The method as recited in claim 25 wherein the authentication request
2 originates with the endpoint.

1 27. The method as recited in claim 26 wherein the connection between the
2 feature server providing the information stream and the endpoint includes an egress
3 point of the packet switched network.

1 28. An apparatus comprising:
2 a packet switched network including one or more egress points coupled to an
3 external telephone network; and
4 a feature platform coupled to control outgoing calls for call agents, the
5 outgoing calls connecting respective destination numbers and

6 respective ones of the call agents through egress points, connections
7 between the destination numbers and the respective calling agents
8 being independent of the feature platform after each of the calls is
9 connected.

CENTRALIZED FEATURE PLATFORM IN A PACKETIZED NETWORK

Husnain Bajwa
Samuel R. Shiffman
J. Michael Holloway

5 ABSTRACT OF THE DISCLOSURE

10 A packetized telecommunication network directs a call that is received at a gateway of the network to connect to a feature platform via the network, which performs a service related to the call, such as an authentication service. After the service is performed, the call is redirected to another location in the network to provide a connection between the gateway and the other location, which connection is independent of the feature platform.
